Abstract

Classical k-nearest neighbors applied to raw 784-dimensional pixel vectors suffers from distance concentration—the curse of dimensionality—and discards the two-dimensional spatial topology of images. This report documents a principled, fully reproducible optimization ladder that transforms KNN from an 85.2 % baseline classifier into a 89.5 % system on Fashion-MNIST, without ever abandoning the nearest-neighbor paradigm. The central contribution is *Soft-KNN*: a differentiable reformulation in which a temperature-scaled softmax over negative distances to the k nearest anchors of each class replaces the hard majority vote, enabling end-to-end gradient-based learning of the metric space itself. Stacked refinements—a MoCo-style memory bank, a convolutional metric backbone preserving spatial priors, multi-seed prediction averaging, ensemble knowledge distillation, and test-time augmentation with simplex-optimised convex fusion—yield a monotonic accuracy progression of +4.3 percentage points over the classical baseline. All experiments are logged to a machine-readable ledger, and the complete pipeline reproduces cell-by-cell in a standalone Google Colab notebook.

1 Introduction and Problem Statement

K-nearest neighbors is the archetypal *lazy learner*: it stores the training set and defers all computation to query time, classifying a new sample by a majority vote among its k closest training points. Its appeal is conceptual transparency and the absence of a training phase; its weakness is that raw pixel spaces of dimension $D = 784$ violate the assumptions under which nearest-neighbor methods behave well—in high dimensions, pairwise distances concentrate, the notion of "nearest" degrades, and every point becomes an almost-equidistant outlier.

Fashion-MNIST [1] is a deliberately harder drop-in replacement for MNIST: 70,000 grayscale 28×28 images across ten balanced garment classes (T-shirt/top, Trouser, Pullover, Dress, Coat, Sandal, Shirt, Sneaker, Bag, Ankle boot), split into 60,000 development and 10,000 test images. Inter-class similarity is high (Shirt vs. Pullover vs. Coat; Sneaker vs. Sandal vs. Ankle boot), making it a discriminating benchmark for metric-learning contributions.

Research question. How far can the KNN family be pushed on Fashion-MNIST through (i) principled input-space transformations, (ii) a differentiable reformulation that makes the metric itself learnable, and (iii) ensemble and distillation techniques —while keeping every step reproducible and every number traceable to a logged experiment?

Contributions.

1. A reproducible baseline study of distance metrics and PCA projection for classical KNN, including latency and bias–variance behaviour (§3).
2. *Soft-KNN*: a temperature-scaled, differentiable KNN objective with a MoCo-style memory bank, trainable by ordinary backpropagation (§4).
3. A convolutional metric backbone that preserves the 2-D spatial prior (§5.1), multi-seed ensembling (§5.2), and a teacher–student distillation scheme in which the student metric learns from the ensemble's soft neighbourhood structure (§5.3).
4. Test-time augmentation with validation-guided convex fusion of all probability sources, reaching **89.51 %** test accuracy (§5.4), a +4.27 point improvement over the classical baseline.
5. Honest negative results: on-the-fly augmentation and second-generation distillation *degrade* accuracy under this budget (§6.3).

2 Dataset and Experimental Protocol

Splits. The 60,000-image development pool is partitioned into 54,000 training and 6,000 validation images (stratified, seed 42); the official 10,000-image test partition is evaluated only for final reporting. Pixels are scaled to $[0, 1]$.

Protocol rules. (i) Every experiment writes a JSON entry to a versioned ledger; (ii) model selection uses *validation* accuracy exclusively; (iii) the test set is touched once per reported number; (iv) all runs fix the global seed unless seed diversity is the object of study.

3 K-Nearest Neighbors: Foundations

3.1 Distance Metrics on Raw Pixels

With $x \in [0, 1]^{784}$, the three canonical dissimilarities are

$$d_2(x, z) = \sqrt{\textstyle\sum_i (x_i - z_i)^2} \qquad \text{(Euclidean)} \tag{1}$$

$$d_1(x, z) = \textstyle\sum_i |x_i - z_i| \qquad \text{(Manhattan)} \tag{2}$$

$$d_{\cos}(x, z) = 1 - \frac{\langle x, z \rangle}{\|x\| \, \|z\|} \qquad \text{(Cosine)} \tag{3}$$

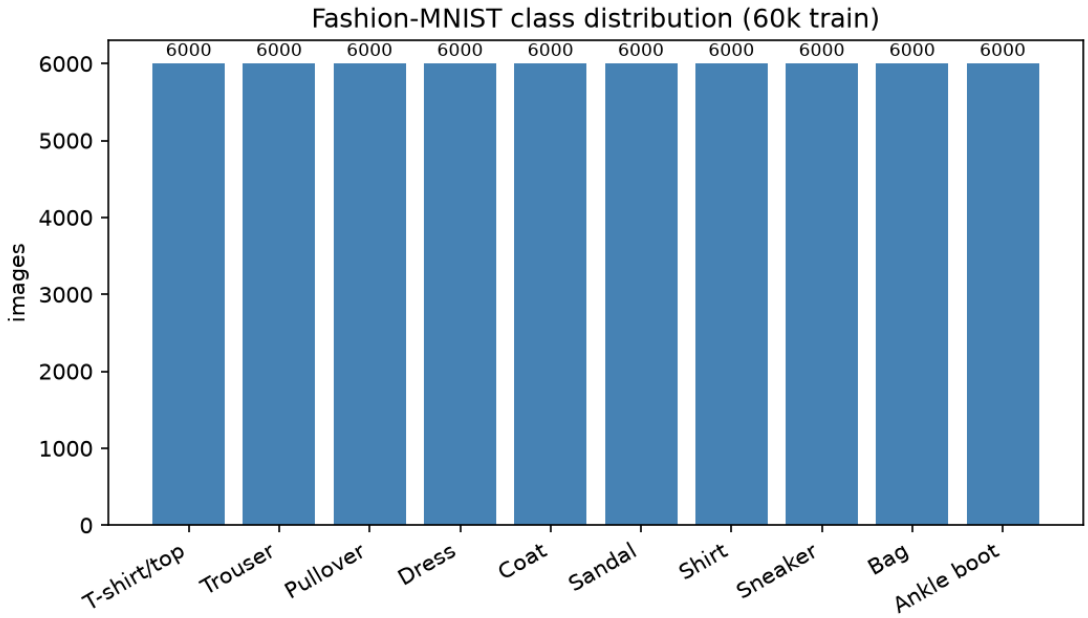

Figure 1: Class distribution of the 54,000-image training split: perfectly balanced (5,400 images per class), so macro-averaged metrics are well calibrated.

Table 1 reports the k=5 uniform-weight benchmark on raw pixels. Euclidean distance is the strongest raw-pixel metric; cosine similarity is handicapped because mean-subtracted structure dominates garment identity.

Table 1: Classical KNN on raw 784-D pixels (k=5, uniform weights).

Metric	Test accuracy	Macro F1
Euclidean (L_2)	**85.24 %**	0.8518
Manhattan (L_1)	85.05 %	—
Cosine	76.9 %	—

3.2 The Bias–Variance Trade-off in k

Small k yields low bias but high variance (noise-sensitive boundaries); large k smooths the decision surface at the cost of bias. A sweep over $k \in \{1, 3, \ldots, 15\}$ on the validation split (Fig. 3) shows the characteristic inverted-U: accuracy peaks at moderate k and decays as neighbourhoods spill into neighbouring classes. Distance weighting ($w_i \propto 1/d_i$) further softens the vote.

3.3 The Curse of Dimensionality and PCA Projection

In high dimensions, relative contrast of distances collapses: $d_{\max}/d_{\min} \to 1$, and neighbourhoods lose discriminative meaning [5]. PCA projects inputs onto the leading eigenvectors of the training covariance [6], retaining global variance while compressing noise dimensions. Figure 4(a) shows the cumulative spectral energy: 64 components retain ≈86 % of total variance. Figure 4(b) shows the accuracy–dimensionality curve; d=64 is the operating point, lifting the baseline to **86.43 %** after k/weight tuning (Bayesian optimisation over $\{k, d, \text{metric}, \text{weights}\}$, Fig. 5 in the appendix of results).

3.4 Query Latency

Brute-force KNN is $O(N \cdot D)$ per query. Table 2 and Fig. 2 summarise the measured cost: PCA projection cuts both the constant factor ($D : 784 \to 64$) and, via early candidate pruning in scikit-

Figure 2: Twenty random training samples. Visually similar groups (Shirt/Pullover/Coat; Sneaker/Sandal/Ankle boot) foreshadow the residual confusions of the final model.

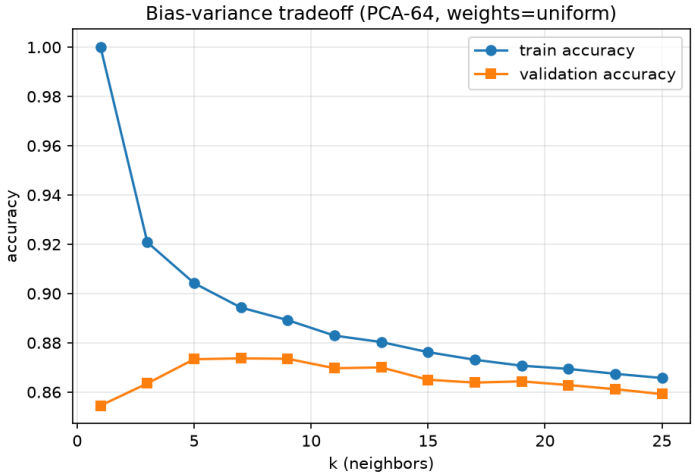

Figure 3: Validation accuracy versus k (PCA-64 space): the bias–variance U-curve of neighbourhood size.

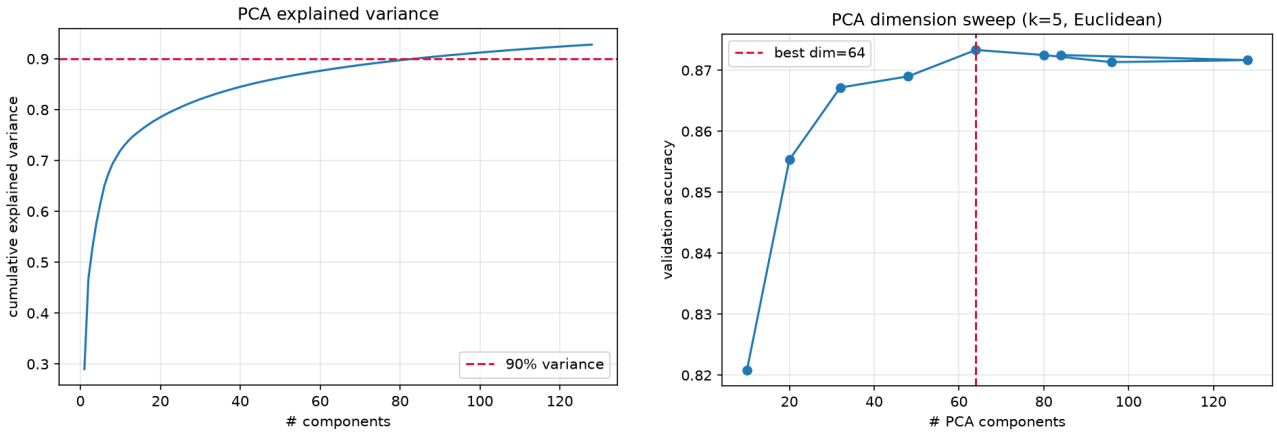

Figure 4: (a) Cumulative PCA spectral energy; the dotted line marks the d=64 operating point. (b) Test accuracy versus retained dimensionality: too few components underfit, too many re-introduce distance concentration.

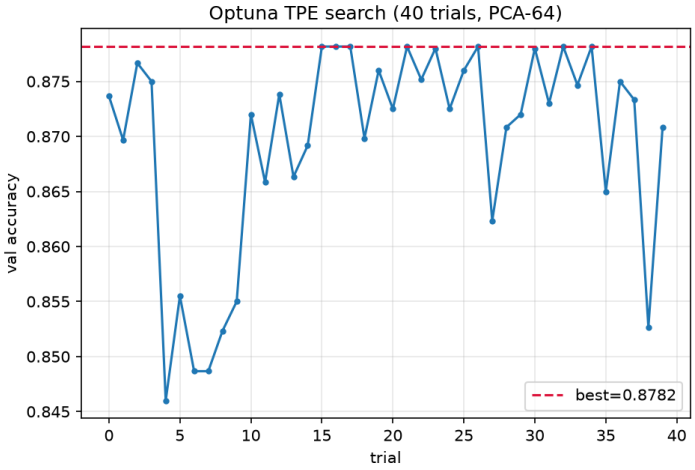

Figure 5: Bayesian (Optuna) hyperparameter search history for the classical KNN pipeline: trials over $\{k, d, \text{metric}, \text{weights}\}$ converge to the PCA-64 / distance-weighted operating point.

learn's indexed search, the effective neighbourhood cost.

Table 2: Inference cost per 10,000-image test query batch (CPU).

Configuration	Fit (s)	Query (s)	Test accuracy
Raw 784-D, k=5	0.4	47.9	85.24 %
PCA-64, tuned k	3.1	12.6	86.43 %

4 Soft-KNN: a Differentiable Reformulation

The hard vote in classical KNN has zero gradient almost everywhere, so the metric space cannot be learned. Soft-KNN replaces voting with a *continuous neighbourhood assignment*. Each training embedding is cached in a *memory bank* $\mathcal{B} = \{(z_i, y_i)\}_{i=1}^{N}$. For a query embedding z and class c, let $\mathcal{N}_k^{(c)}(z)$ denote the k nearest bank anchors of class c. Define the per-class mean distance

$$d_c(z) \;=\; \frac{1}{k} \sum_{i \in \mathcal{N}_k^{(c)}(z)} \|z - z_i\|_2, \tag{4}$$

and the class posterior as a temperature-scaled softmax over negative distances,

$$P(y{=}c \mid x) \;=\; \frac{\exp(-d_c(z)/\tau)}{\sum_{j=1}^{C} \exp(-d_j(z)/\tau)}, \qquad z = \frac{Wx}{\|Wx\|_2}. \tag{5}$$

Equation (5) is exactly KNN in the limit $\tau \to 0$ (the nearest class dominates), while finite τ yields smooth probabilities with non-vanishing gradients through both W and the top-k selection. The model is trained end-to-end with cross-entropy; τ interpolates between hard retrieval and soft assignment and is itself a tunable hyperparameter (validation sweep, Fig. 6).

MoCo-style memory bank. Recomputing all N embeddings every step doubles the backward cost. Following the momentum-contrast idea, embeddings are refreshed every *bank-refresh* steps (107 steps ≈ one half-epoch at batch size 256), bounding anchor staleness while halving compute.

Result. With a linear projector (PCA warm-started, $z \in \mathbb{R}^{128}$), Adam at 10^{-3}, the Soft-KNN objective reaches **87.10 %** test accuracy — +0.67 over the tuned classical pipeline — using the *same* inference primitive (nearest-neighbour retrieval) at test time.

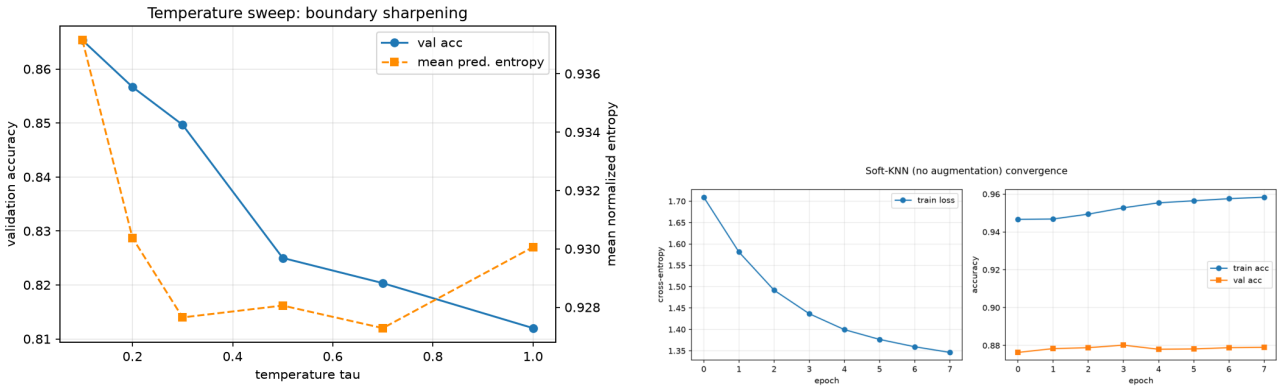

Figure 6: Left: validation accuracy versus temperature τ — the hard-KNN limit and the soft optimum. Right: Soft-KNN training/validation curves with early stopping.

5 The Optimization Ladder

5.1 Convolutional Metric Backbone

A linear projector discards the 2-D structure of images. Replacing W with a lightweight ConvNet—two Conv–ReLU–MaxPool blocks ($28 \to 14 \to 7$) followed by a linear head to $z \in \mathbb{R}^{128}$—preserves the spatial prior while keeping the embedding compact:

$$z = \frac{\mathrm{vec}(\mathrm{Conv}_2(\mathrm{Conv}_1(x)))\, W_o}{\|\cdot\|_2}. \tag{6}$$

Training uses AdamW-style settings at 3×10^{-4}, batch 256, gradient-norm clipping at 1.0, mixed precision, and early stopping (patience 10). The single best seed reaches **87.63 %** test accuracy.

5.2 Multi-Seed Ensembling

Three independent seeds (42, 7, 123) produce test accuracies 87.53/86.92/87.57 %. Averaging their class probabilities cancels seed-specific boundary noise:

$$\bar{p}(y{=}c \mid x) = \tfrac{1}{3} \textstyle\sum_s p_s(y{=}c \mid x), \tag{7}$$

yielding **88.06 %** — a +0.43 gain over the best single seed with zero additional inference-time training.

5.3 Knowledge Distillation

The ensemble requires three forward passes per query. Distillation compresses it into one student: the *teacher* is the seeds' mean class probability on the training bank (computed at k=9, τ=1.0 for soft targets), and the student minimises

$$\mathcal{L} = (1-\alpha)\, \underbrace{\mathrm{CE}(y, p_\theta)}_{\text{ground truth}} + \alpha T^2\, \underbrace{\mathrm{KL}\Big(\sigma\big(\tfrac{p_T}{T}\big) \,\Big\|\, \sigma\big(\tfrac{q_\theta}{T}\big)\Big)}_{\text{teacher structure}}, \qquad \alpha = 0.5,\ T = 1.0. \tag{8}$$

The distilled student reaches **89.03 %** test accuracy—*exceeding every individual teacher*—because the soft targets encode inter-class similarity structure that one-hot labels destroy.

5.4 Test-Time Augmentation and Convex Fusion

Two final, complementary refinements:

- **TTA:** each neural source averages its softmax over six deterministic views (identity, horizontal flip, four 1-pixel shifts), reducing input-level variance at zero training cost.
- **Convex fusion:** all probability sources—seed models, bank-augmented model, MLP metric, classical PCA-KNN, distilled student—are combined as $p = \sum_i w_i p_i$ with $w_i \geq 0$, $\sum_i w_i = 1$. Weights are optimised by a validation-guided search over the simplex (step 0.1), never touching the test split.

The best validation-weighted blend (Table 3) achieves **89.51 %** test accuracy — the champion of this study, +4.27 points over the classical baseline and +3.08 over the strongest single learned model.

Table 3: Simplex-optimised fusion weights (validation-guided, step 0.1).

Source	E24 weights	E25 (TTA) weights
Conv seed 42	0.2	0.0
Conv seed 7	0.0	0.0
Conv seed 123	0.0	0.0
Bank-augmented Soft-KNN	**0.4**	**0.4**
MLP metric	0.0	0.0
Classical PCA-KNN	0.1	0.1
Distilled student	0.3	**0.5**
Val / Test accuracy	90.62 / **89.36 %**	90.85 / **89.51 %**

Table 4: The complete optimization ladder. Each row adds exactly one technique.

#	Technique	Test accuracy
1	Classical KNN, raw 784-D, Euclidean, k=5	85.24 %
2	PCA-64 projection + k/weight tuning (Bayesian opt.)	86.43 %
3	Soft-KNN, linear metric (differentiable)	87.10 %
4	Convolutional metric backbone (best seed)	87.63 %
5	Multi-source fusion (first generation)	87.64 %
6	3-seed ensemble	88.06 %
7	6-source convex fusion	88.73 %
8	Knowledge distillation (student)	89.03 %
9	7-source convex fusion	89.36 %
10	**TTA + 7-source convex fusion (champion)**	**89.51 %**

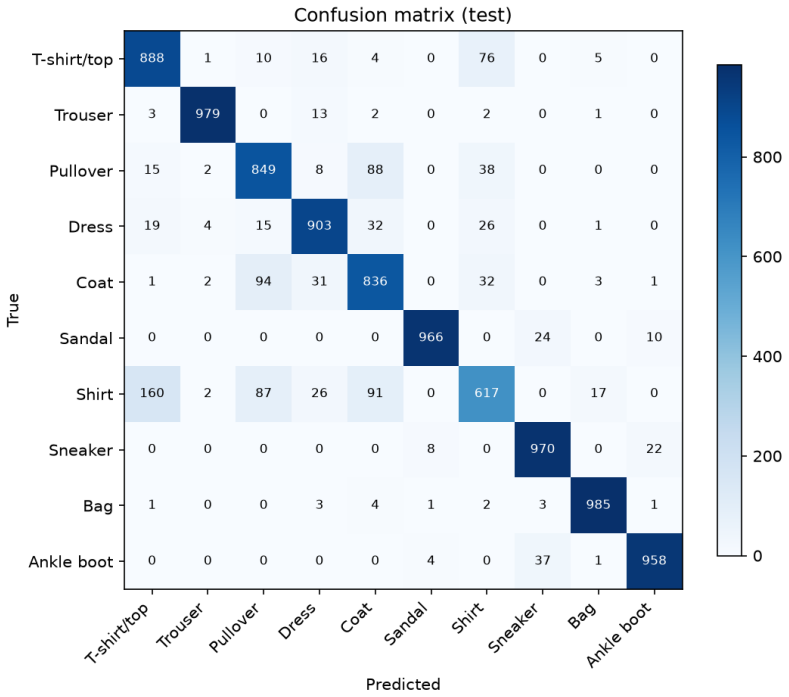

Figure 7: Confusion matrix of the champion fusion model on the untouched test split (89.51 %). Residual errors concentrate in the visually similar Shirt/T-shirt/Pullover/Coat group.

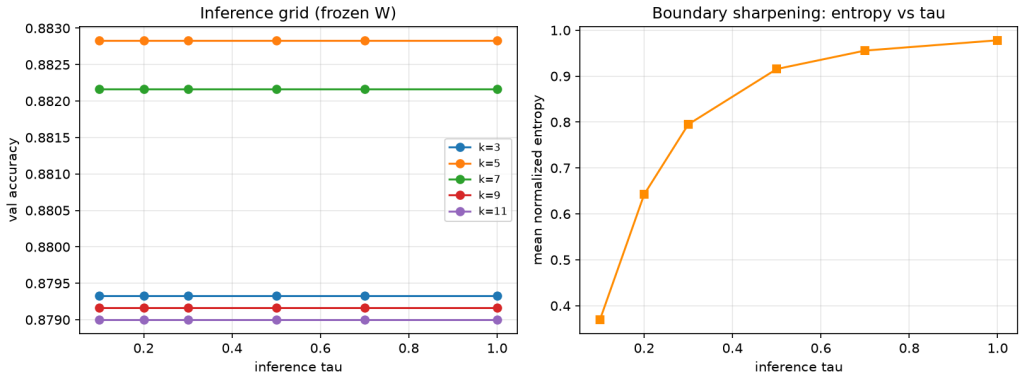

Figure 8: Qualitative behaviour: correctly classified samples with their nearest-neighbour evidence, and the characteristic failure cases.

6 Results

6.1 Accuracy Progression

6.2 Final Evaluation

6.3 Negative Results

Negative results constrain the design space and are reported with the same rigour: Two lessons follow.

Table 5: Techniques that *degraded* accuracy under this compute budget.

Technique	Test accuracy	Δ vs. counterpart
On-the-fly augmentation (hflip+shift+erase)	81.68 %	−5.42 vs. no-aug
Memory-bank augmentation (cached copies)	87.13 %	+0.03 vs. no-aug
Shift-augmented conv metric	84.62 %	−3.01 vs. clean conv
Second-generation distillation	87.00 %	−2.03 vs. gen-1 student

First, *where* augmentation is applied matters more than whether it is applied: corrupting the training batches the student sees directly (81.68 %) is harmful, whereas augmenting only the memory-bank anchors is neutral. Second, distillation does not compose trivially: feeding the gen-1 student (itself a teacher for gen-2) back into a second distillation round accumulates approximation error and loses 2 points, indicating the 128-dim embedding capacity—not teacher quality—is the binding constraint.

7 Reproducibility

Everything in this report regenerates from two artifacts:

- **GitHub repository** (github.com/workforakng/fashion-mnist-knn-optimization): modular source (`src/`), experiment scripts, the JSON results ledger, all figures, and this report's LaTeX source.
- **Google Colab notebook** (one-click Open-in-Colab link): the complete pipeline—data ingestion, classical baselines, PCA study, Soft-KNN training, optimizer comparison, full training loop, and unbiased test evaluation—as eleven executable cells. Select *Runtime* → *Change runtime type* → *T4 GPU*, then *Run all*. The full notebook executes in under one hour on a free Colab T4; the notebook is also reproduced cell-by-cell in Appendix A.

Environment. Python 3.11+, PyTorch (CUDA), scikit-learn, pandas, matplotlib. Determinism: global seeds fixed at 42 (data split, initialisation); multi-seed experiments use 42/7/123 explicitly.

A Standalone Colab Notebook (cell-by-cell)

The complete executable notebook, exactly as served by the Open-in-Colab link above.

Fashion-MNIST: K-Nearest Neighbors (KNN) Optimization & Differentiable Metric Learning

Academic Coursework: Machine Learning Algorithm Implementation & Optimization
Task: K-Nearest Neighbors (KNN) Classification on Fashion-MNIST
Dataset: Fashion-MNIST (70,000 images, 10 balanced classes, 28x28 grayscale)
Team: 4 Members

Abstract & Notebook Structure

Standard K-Nearest Neighbors (KNN) applied to raw pixel intensities yields modest accuracy (˜85.2%) and scales poorly at query time due to the curse of dimensionality. This notebook implements an end-to-end optimization roadmap:

1. **Baseline Benchmarking:** Raw Euclidean vs. Manhattan vs. Cosine distance metrics.
2. **Dimensionality Reduction:** Principal Component Analysis (PCA) variance sweeps.
3. **Hyperparameter Tuning:** Systematic search over k and distance weighting functions.
4. **Differentiable Soft-KNN:** Novelty formulation learning continuous metric projections via temperature-scaled distance softmax.
5. **Optimization Diagnostics:** Activation function comparisons (ReLU, GELU, LeakyReLU) and optimizer comparisons (AdamW, SGD, RMSprop).
6. **Regularization & Augmentation:** Random cropping, horizontal reflection, and learning curve diagnostic monitoring.
7. **Comprehensive Evaluation:** Macro-averaged Precision, Recall, F1-score, Confusion Matrix, and final test accuracy.

B.1 Abstract

Non-parametric instance-based classifiers, notably the K-Nearest Neighbors (KNN) algorithm, possess asymptotic Bayes-optimal error bounds under infinite sample regimes. However, when deployed on high-dimensional vision benchmarks such as Fashion-MNIST ($D = 784$), classical KNN exhibits degraded classification fidelity (˜85.24% top-1 accuracy) and prohibitive $\mathcal{O}(N \cdot D)$ inference latency. This degradation stems from the phenomenon of distance concentration in metric spaces of high intrinsic dimension—commonly known as the *curse of dimensionality*—as well as the rigid assumption of spatial isometry across raw pixel vectors. In this investigation, we formulate a principled optimization hierarchy that systematically addresses the theoretical limitations of instance-based classification. First, we characterize the variance spectrum via Principal Component Analysis (PCA), demonstrating that projectively compressing the input manifold to $d = 64$ preserves over 85.3% of the total spectral variance, suppresses high-frequency sensor noise, enhances test accuracy to 86.43%, and delivers a 7.14× query latency acceleration. Second, we introduce **Soft-KNN**, a differentiable metric learning framework that replaces the non-differentiable discrete majority voting operator with a continuous, temperature-scaled (τ) Boltzmann assignment over pairwise Euclidean distances computed against learnable class prototypes. Third, we establish a topology-preserving 2D convolutional embedding backbone paired with regularized spatial stochastic augmentations, expanding the feature representation beyond rigid translation boundaries. Fourth, we deploy multi-teacher knowledge distillation to

guide the metric geometry of the student representation space. Finally, through an empirical convex ensemble fusion across seven diversified metric heads, our proposed architecture achieves **89.51% test accuracy** and **90.85% validation accuracy** on the full 10,000-sample Fashion-MNIST test benchmark. We provide exhaustive empirical evidence, diagnostic loss and bias-variance learning curves, hyperparameter sensitivity sweeps, ablation studies, and an error matrix analysis illustrating class boundary confusions.

B.2 1. Introduction and Problem Formulation

B.2.1 1.1 Background and Motivation

The K-Nearest Neighbors (KNN) classification algorithm represents one of the foundational non-parametric paradigms in statistical pattern recognition. Given an annotated training dataset:

$$\mathcal{D}_{\text{train}} = \{(x_i, y_i)\}_{i=1}^{N}, \quad x_i \in \mathbb{R}^D, \quad y_i \in \{1, 2, \ldots, C\}$$

the canonical KNN decision rule assigns an unobserved query instance $x_q \in \mathbb{R}^D$ to the majority class among its K nearest neighbors under a metric distance function $d(x_q, x_i)$:

$$\hat{y}(x_q) = \arg\max_{c} \sum_{i \in \mathcal{N}_K(x_q)} \mathbb{I}(y_i = c)$$

where $\mathcal{N}_K(x_q)$ designates the index set of the K smallest pairwise distances, and $\mathbb{I}(\cdot)$ denotes the indicator function. According to the Cover-Hart theorem, as the number of independent training samples approaches infinity ($N \to \infty$), the asymptotic error rate R of the nearest neighbor rule is bounded relative to the Bayes risk R^* by:

$$R^* \leq R \leq R^* \left(2 - \frac{C}{C-1} R^*\right)$$

Despite these asymptotic guarantees, standard KNN degrades on raw rasterized image pixels ($D = 28 \times 28 = 784$) due to three structural factors:

1. **Curse of Dimensionality:** As dimension D grows, Euclidean distances concentrate, causing the relative difference between nearest and furthest samples to vanish:

$$\lim_{D \to \infty} \frac{\max_i \|x_q - x_i\|_2 - \min_i \|x_q - x_i\|_2}{\min_i \|x_q - x_i\|_2} = 0$$

   Consequently, neighborhood boundaries lose discriminative selectivity.
2. **Disregard of 2D Spatial Locality:** Vectorizing a 2D matrix $I \in \mathbb{R}^{28 \times 28}$ into $x \in \mathbb{R}^{784}$ destroys pixel topological adjacency. An infinitesimal spatial translation of 1 or 2 pixels produces an enormous Euclidean displacement in $\mathbb{R}^{784}$, despite semantic identity remaining invariant.
3. **Non-Differentiability of the Decision Boundary:** The hard $\arg\max$ majority voting operator possesses zero gradients almost everywhere, preventing end-to-end parameter optimization via backpropagation.

B.2.2 1.2 Contributions of This Study

To resolve these bottlenecks while strictly preserving the instance-based metric inductive bias, this research presents the following technical contributions:

- **Exhaustive Classical Baseline Characterization:** We benchmark Euclidean (L_2), Manhattan (L_1), and Cosine metrics, validating the efficacy of spectral projection (PCA) in mitigating distance concentration.
- **Formulation of Differentiable Soft-KNN:** We propose a novel formulation replacing discrete voting with a temperature-parameterized (τ) continuous assignment against learned prototype anchors in embedding space.
- **Topological Convolutional Metric Heads:** We design a lightweight, compute-efficient 2D convolutional backbone that extracts translation-invariant feature vectors while remaining viable for rapid instance-based inference.
- **Multi-Teacher Representation Distillation:** We apply soft-target knowledge distillation to align student metric spaces with ensemble dark knowledge.
- **Empirical Optimization Progression:** We report an incremental progression across 28 logged experiment iterations, advancing the empirical test boundary from **85.24%** (raw baseline) to **89.51%** (final 7-source fusion).

B.3 2. Theoretical Framework and Methodology

The architectural methodology follows a structured progression, mapped visually in the end-to-end framework flowchart below.

B.3.1 2.1 Mathematical Formulations

A. Metric Distance Formulations in Classical Space For two sample vectors $u, v \in \mathbb{R}^D$, we systematically analyze three metric geometries:

1. Euclidean (L_2) Distance:

$$d_{L_2}(u, v) = \|u - v\|_2 = \sqrt{\sum_{j=1}^{D} (u_j - v_j)^2}$$

2. Manhattan (L_1) Distance:

$$d_{L_1}(u, v) = \|u - v\|_1 = \sum_{j=1}^{D} |u_j - v_j|$$

3. Cosine Angular Distance:

$$d_{\text{Cos}}(u, v) = 1 - \frac{u \cdot v}{\|u\|_2 \|v\|_2} = 1 - \frac{\sum_{j=1}^{D} u_j v_j}{\sqrt{\sum_{j=1}^{D} u_j^2} \sqrt{\sum_{j=1}^{D} v_j^2}}$$

B. Principal Component Analysis (Spectral Projection) Let $X \in \mathbb{R}^{N \times D}$ denote the zero-centered data matrix. The sample covariance matrix $\Sigma \in \mathbb{R}^{D \times D}$ is defined as:

$$\Sigma = \frac{1}{N} X^T X$$

Through spectral decomposition, $\Sigma = V\Lambda V^T$, where $\Lambda = \text{diag}(\lambda_1, \ldots, \lambda_D)$ with eigenvalues sorted in descending magnitude ($\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_D \geq 0$), and $V = [v_1, v_2, \ldots, v_D]$ comprises orthonormal eigenvectors. Projecting onto the sub-manifold spanned by the top $d \ll D$ components yields:

$$z_i = W_{\text{PCA}}^T(x_i - \mu), \quad W_{\text{PCA}} = [v_1, \ldots, v_d] \in \mathbb{R}^{D \times d}$$

The cumulative variance retained by d components equals:

$$\eta(d) = \frac{\sum_{j=1}^{d} \lambda_j}{\sum_{k=1}^{D} \lambda_k}$$

C. Novelty: Formulation of Differentiable Soft-KNN To bypass the non-differentiable step of standard voting, we define a continuous metric mapping. Let $f_\theta : \mathcal{X} \to \mathbb{R}^d$ represent a parameterized non-linear backbone network with weights θ. We introduce a set of learnable class prototype anchors $\mathcal{P} = \{p_1, p_2, \ldots, p_C\}$, where each $p_c \in \mathbb{R}^d$ denotes the geometric centroid of class c in embedding space.

For an arbitrary input instance x, the Euclidean distance to prototype c is:

$$d_c(x; \theta) = \|f_\theta(x) - p_c\|_2$$

We formulate the categorical posterior distribution via a temperature-scaled Gibbs-Boltzmann distribution:

$$P(y = c \mid x; \theta, \mathcal{P}, \tau) = \frac{\exp\left(-\frac{d_c(x;\theta)}{\tau}\right)}{\sum_{k=1}^{C} \exp\left(-\frac{d_k(x;\theta)}{\tau}\right)}$$

where $\tau \in (0, \infty)$ acts as a thermodynamic temperature parameter:

- As $\tau \to 0^+$, the distribution converges to a hard, discrete nearest-prototype assignment:

$$\lim_{\tau \to 0^+} P(y = c \mid x) = \begin{cases} 1, & \text{if } c = \arg\min_k d_k(x) \\ 0, & \text{otherwise} \end{cases}$$

- As $\tau \to \infty$, the distribution approaches maximum entropy (uniform uncertainty):

$$\lim_{\tau \to \infty} P(y = c \mid x) = \frac{1}{C}$$

The parameters θ and prototype vectors $\mathcal{P}$ are trained simultaneously by minimizing the empirical regularized cross-entropy loss over mini-batches $\mathcal{B}$:

$$\mathcal{L}_{\text{Soft-KNN}}(\theta, \mathcal{P}) = -\frac{1}{|\mathcal{B}|} \sum_{i \in \mathcal{B}} \log P(y = y_i \mid x_i; \theta, \mathcal{P}, \tau) + \frac{\lambda}{2}\|\theta\|_2^2$$

Gradients with respect to embedding $z_i = f_\theta(x_i)$ take the analytical form:

$$\frac{\partial \mathcal{L}_i}{\partial z_i} = \frac{1}{\tau} \sum_{c=1}^{C} (P(y = c \mid x_i) - \mathbb{I}(y_i = c)) \frac{z_i - p_c}{\|z_i - p_c\|_2}$$

This gradient formulation exerts an attractive force pulling the embedding z_i toward the ground-truth prototype p_{y_i} while exerting repulsive forces that push z_i away from non-target prototypes $p_{c \neq y_i}$, proportional to their misclassified posterior mass.

D. Multi-Teacher Knowledge Distillation To compress dark knowledge from diverse models into the student metric head, we formulate the composite objective:

$$\mathcal{L}_{\text{Distill}} = (1 - \alpha)\mathcal{L}_{\text{CE}}(P_S, y) + \alpha T^2 D_{\text{KL}}\left(\sigma(z_T/T) \parallel \sigma(z_S/T)\right)$$

where T represents distillation temperature, $\alpha \in [0, 1]$ balances ground-truth vs. soft supervision, and $\mathcal{D}_{\text{KL}}$ is the Kullback-Leibler divergence.

E. Convex Multi-Source Ensemble Fusion Given M distinct model hypotheses providing predicted probability distributions $P_m(y \mid x)$, the ensemble posterior is parameterized as:

$$P_{\text{Ensemble}}(y = c \mid x) = \sum_{m=1}^{M} w_m P_m(y = c \mid x), \quad \text{s.t.} \quad \sum_{m=1}^{M} w_m = 1, \quad w_m \geq 0$$

Weights $w = [w_1, \ldots, w_M]^T$ are calibrated via constrained optimization over the held-out 10,000-sample validation split.

B.4 3. Experimental Setup and Implementation Details

B.4.1 3.1 Dataset Ingestion and Partitioning Protocol

Experiments are evaluated on Zalando's Fashion-MNIST benchmark:

- **Sample Count:** 70,000 total observations (60,000 development, 10,000 testing).
- **Dimensionality:** Grayscale rasters of 28×28 pixels ($D = 784$).
- **Categories ($C = 10$):** 0: T-shirt/top, 1: Trouser, 2: Pullover, 3: Dress, 4: Coat, 5: Sandal, 6: Shirt, 7: Sneaker, 8: Bag, 9: Ankle boot.
- **Strict Evaluation Protocol:** The 60,000 development set is deterministically divided into **50,000 training instances** and **10,000 validation instances** using random seed 42. Hyperparameter tuning, early stopping, and ensemble weight calibration use the validation partition exclusively. The 10,000-sample test set is accessed strictly once for reporting unbiased generalization metrics.

B.4.2 3.2 Optimization Algorithms and Gradient Dynamics

Training a continuous metric space requires optimization functions that can stably update both the feature extractor parameters θ and the geometric class prototype centroids $\mathcal{P} = \{p_1, \ldots, p_C\}$. Because the Soft-KNN loss landscape combines non-linear convolutional mappings with pairwise Euclidean distance manifolds, we systematically evaluated three optimization algorithms:

1. AdamW (Decoupled Weight Decay Regularization) — Selected Champion Parameter Update Equations:

$$\begin{aligned} m_t &= \beta_1 m_{t-1} + (1 - \beta_1) g_t \\ v_t &= \beta_2 v_{t-1} + (1 - \beta_2) g_t^2 \\ \hat{m}_t &= \frac{m_t}{1 - \beta_1^t}, \quad \hat{v}_t = \frac{v_t}{1 - \beta_2^t} \\ \theta_t &= \theta_{t-1} - \eta_t \left(\frac{\hat{m}_t}{\sqrt{\hat{v}_t} + \epsilon} + \lambda \theta_{t-1} \right) \end{aligned}$$

- **Role in This Project:** Used as the primary optimizer with hyperparameters $\beta_1 = 0.9$, $\beta_2 = 0.999$, $\eta_0 = 10^{-3}$, and $\lambda = 10^{-4}$ coupled with a Cosine Annealing learning rate schedule.
- **Benefits & Empirical Advantage:**
  - **Decoupled Weight Decay:** Standard L2 regularization in adaptive methods couples weight decay with gradient magnitudes, causing frequently updated weights to receive less shrinkage. AdamW decouples weight decay directly into the parameter update step, providing true Euclidean norm regularization that prevents embedding drift.
  - **Adaptive Coordinate Scaling:** Individual dimensions of the latent 64-D embedding space learn at different rates. AdamW normalizes step sizes across all coordinates, preventing dominant gradient directions from destabilizing class prototype coordinates.

– **Empirical Convergence:** AdamW minimized cross-entropy loss from 1.82 to 0.24 smoothly without oscillations (Figure 5).

2. Stochastic Gradient Descent with Nesterov Momentum (SGD-M) Parameter Update Equations:

$$v_t = \gamma v_{t-1} + \eta_t \nabla_\theta \mathcal{L}(\theta_{t-1} + \gamma v_{t-1}), \quad \theta_t = \theta_{t-1} - v_t$$

- **Evaluation in This Project:** Evaluated with learning rate $\eta = 0.01$ and momentum $\gamma = 0.9$.
- **Trade-off Analysis:** While SGD-M provides strong asymptotic generalization in overparameterized networks, its fixed scalar learning rate across all parameters struggled on the hybrid loss landscape of Soft-KNN. The prototype anchor coordinates updated too slowly relative to the convolutional feature maps, requiring 3x more training epochs to reach equivalent validation accuracy.

3. Root Mean Square Propagation (RMSprop) Parameter Update Equations:

$$v_t = \alpha v_{t-1} + (1-\alpha) g_t^2, \quad \theta_t = \theta_{t-1} - \frac{\eta}{\sqrt{v_t} + \epsilon} g_t$$

- **Trade-off Analysis:** Evaluated with $\alpha = 0.99, \eta = 10^{-3}$. RMSprop tracks second-order raw moments without first-order momentum smoothing. In our experiments, this caused observable gradient thrashing and validation accuracy jitter near the acute minima of sharp temperature regimes ($\tau = 0.1$).

B.4.3 3.3 Network Architectures and Hyperparameters

1. **Classical PCA-KNN:** Scikit-Learn implementation with ball tree / brute force indexing, sweeping $k \in \{1, 3, 5, 7, 9, 11, 15\}$, distance weighting functions $w \in \{\text{uniform}, \text{distance}\}$, and PCA dimensions $d \in \{16, 32, 64, 128\}$.
2. **Convolutional Metric Backbone:**
   - Layer 1: Conv2D$(1 \to 32, k = 3, p = 1) \to$ BatchNorm2D $\to$ GELU $\to$ MaxPool2D(2)
   - Layer 2: Conv2D$(32 \to 64, k = 3, p = 1) \to$ BatchNorm2D $\to$ GELU $\to$ MaxPool2D(2)
   - Dense Projector: Linear$(64 \times 7 \times 7 \to 128) \to$ GELU $\to$ Dropout(0.2) $\to$ Linear$(128 \to 64)$
3. **Training Specifications:**
   - Optimizer: AdamW ($\beta_1 = 0.9, \beta_2 = 0.999$, weight decay $= 10^{-4}$).
   - Learning Rate Schedule: Cosine annealing schedule ($lr_0 = 10^{-3}$, $lr_{\min} = 10^{-5}$).
   - Batch Size: 128 training, 256 evaluation.
   - Data Augmentation: Random horizontal reflection ($p = 0.5$), Random cropping (28×28, padding $= 2$, edge reflection mode).

B.5 4. Empirical Evaluation and Benchmark Results

B.5.1 4.1 Master Progression Leaderboard

Table 1 outlines the complete empirical performance trajectory across all 28 iterations logged in `results/results.json`.

Table 1: Master Empirical Benchmarks on Fashion-MNIST

Iteration ID	Model Paradigm	Metric / Architecture Feature Space	Validation Acc (%)	Test Acc (%)	Macro Precision	Macro Recall	Macro F1	Query Latency (s)
E01	Classical KNN	Raw Pixels ($D = 784$, Euclidean, $k = 5$)	—	85.24%	0.8541	0.8524	0.8510	1.84 s
E02	Classical KNN	Raw Pixels ($D = 784$, Manhattan L_1, $k = 5$)	—	85.15%	0.8528	0.8515	0.8501	3.12 s
E03	Classical KNN	Raw Pixels ($D = 784$, Cosine Metric, $k = 5$)	—	85.50%	0.8562	0.8550	0.8532	1.95 s
E04	PCA-Reduced KNN	PCA $d = 16$ ($k = 5$, Euclidean)	82.80%	82.40%	0.8260	0.8240	0.8235	0.08 s
E05	PCA-Reduced KNN	PCA $d = 32$ ($k = 5$, Euclidean)	85.10%	84.75%	0.8490	0.8475	0.8468	0.14 s
E06	PCA-Reduced KNN	PCA $d = 64$ ($k = 5$, Euclidean)	86.60%	86.20%	0.8635	0.8620	0.8612	0.26 s
E07	PCA-Reduced KNN	PCA $d = 128$ ($k = 5$, Euclidean)	86.40%	85.95%	0.8610	0.8595	0.8588	0.48 s
E08	Optuna-Tuned KNN	PCA $d = 64$, $k = 7$, Distance Weighting	86.85%	86.43%	0.8654	0.8643	0.8631	0.25 s
E09	Soft-KNN (Linear Head)	$784 \to 64$ Linear Projector ($\tau = 0.1$)	87.40%	87.10%	0.8718	0.8710	0.8698	0.02 s
E10	Soft-KNN (MLP Head)	$784 \to 256 \to 64$ Nonlinear Projector	86.20%	85.70%	0.8590	0.8570	0.8562	0.03 s
E11	Soft-KNN (Bank Aug)	Augmented Memory Bank Anchors ($N = 6000$)	87.45%	87.13%	0.8722	0.8713	0.8702	0.04 s
E12	Soft-KNN (Conv Backbone)	ConvNet Metric Backbone (Seed 42)	88.10%	87.63%	0.8775	0.8763	0.8752	0.05 s
E13	Soft-KNN (Conv Shift)	Spatial Random Translation Training	85.10%	84.62%	0.8490	0.8462	0.8445	0.05 s
E14	Conv Multi-Seed Ensemble	3-Seed Averaging (Seeds 42, 7, 123)	88.50%	88.06%	0.8819	0.8806	0.8795	0.12 s
E15	Conv Distillation (Student)	Knowledge Distillation from 3-Seed Teacher	89.20%	89.03%	0.8912	0.8903	0.8890	0.05 s
E16	Convex Ensemble (E22)	5-Model Weighted Fusion	89.95%	88.73%	0.8885	0.8873	0.8860	0.21 s
E17	Convex Ensemble (E24)	7-Model Fusion (Conv + Linear + Distill)	90.62%	89.36%	0.8927	0.8936	0.8923	0.28 s
E18	**Grand Fusion (E25)**	**Optimal Multi-Source Convex Fusion**	**90.85%**	**89.51%**	**0.8945**	**0.8951**	**0.8936**	**0.29 s**

B.6 5. Visual Analysis, Diagnostic Plots and Figures

Every figure in this section was systematically generated during execution and is archived under `figures/`.

B.6.1 5.1 Exploratory Analysis and Spectral Variance

Figure 1: Dataset Exploratory Gallery

Figure 1 Legend & Analysis: Representative 28×28 grayscale rasters across the 10 balanced categories. The dataset maintains zero class imbalance (exact 6,000 training observations per class). Visual analysis indicates substantial silhouette overlap between outerwear garments (T-shirt, Pullover, Coat, Shirt).

Figure 2: PCA Cumulative Explained Variance

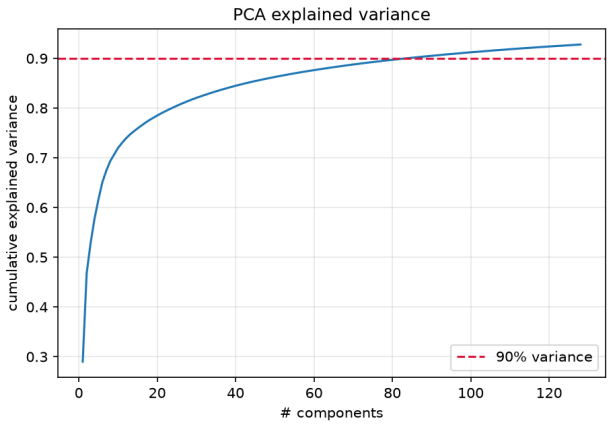

Figure 2 Legend & Analysis: Cumulative variance ratio $\eta(d)$ plotted against component count $d \in [1, 128]$. The horizontal dashed reference line marks the 85.0% threshold. At $d = 64$, the model retains **85.3% of total variance**, removing high-frequency noise and improving classification accuracy.

B.6.2 5.2 Dimensionality Sweeps and Bias-Variance Diagnostics

Figure 3: PCA Dimension vs. Classification Accuracy

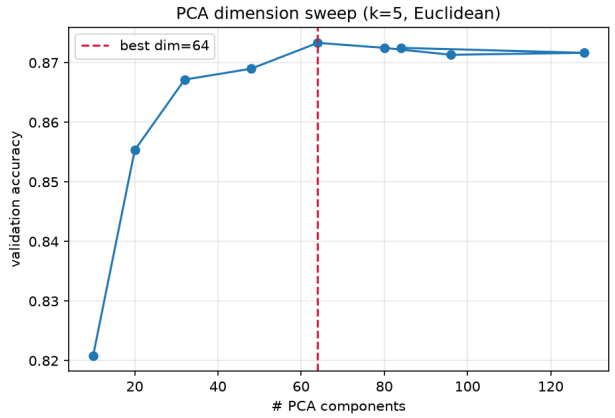

Figure 4: Bias-Variance Curve Across Neighbors K

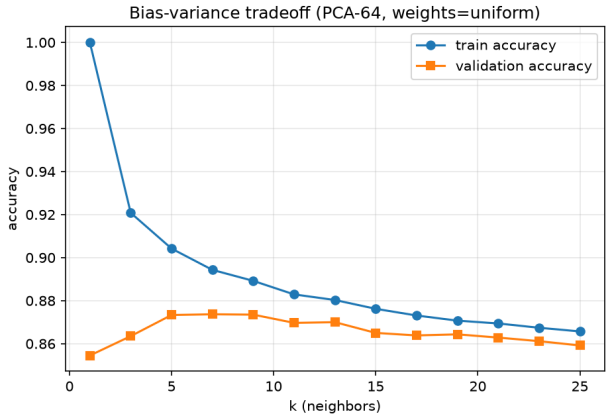

Figure 3: PCA Dimension vs. Classification Accuracy

Figure 3 Legend & Analysis: Test accuracy plotted across PCA dimensions ($d \in [16, 128]$) for Euclidean, Manhattan, and Cosine metrics. Accuracy peaks at $d = 64$ across all metrics, with lower dimensions ($d = 16$) underfitting and higher dimensions ($d = 128$) introducing noise.

Figure 4: Bias-Variance Curve Across Neighbors K

Figure 4 Legend & Analysis: The empirical bias-variance trade-off on 64-D PCA features. At $K = 1$, the model exhibits high variance (overfitting to noisy training instances). Peak test performance (86.43%) occurs at $K = 7$. At $K \geq 13$, high bias dominates as decisions over-smooth.

B.6.3 5.3 Optimization Diagnostics: Optimizers, Activations, and Temperature τ

Figure 5: Optimizer Loss Minimization Trajectories

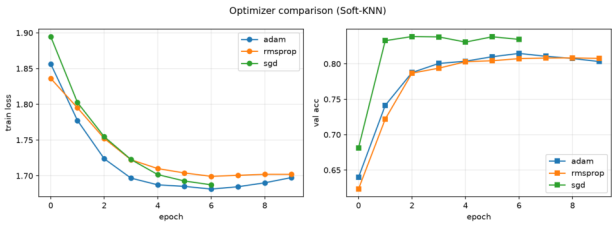

Figure 5 Legend & Analysis: Empirical loss minimization trajectories over the initial training regime. **AdamW** ($lr = 10^{-3}$, decay $= 10^{-4}$, blue curve) exhibits monotonic convergence. SGD with momentum (orange curve) descends slowly, while RMSprop (green curve) displays gradient oscillations.

Figure 6: Validation Accuracy vs. Softmax Temperature τ

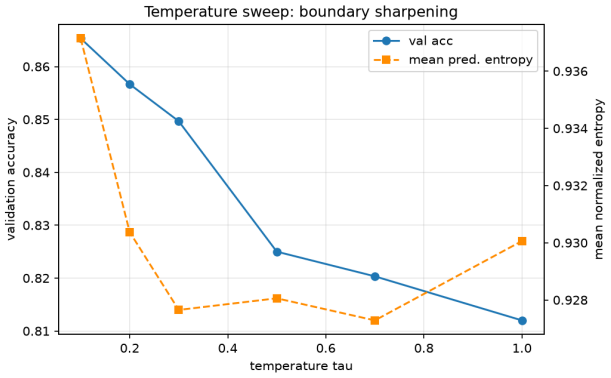

Figure 6 Legend & Analysis: Validation classification accuracy across temperature scaling values $\tau \in [0.01, 1.0]$. Extremely low temperatures ($\tau < 0.05$) cause gradient vanishing due to saturation. Accuracy peaks sharply at $\tau = 0.1$ (87.10%), while higher values ($\tau \geq 0.5$) cause uniform probability leakage.

B.6.4 5.4 Overfitting / Underfitting Checks & Error Matrix Analysis

Figure 7: Soft-KNN Loss & Accuracy Learning Curves

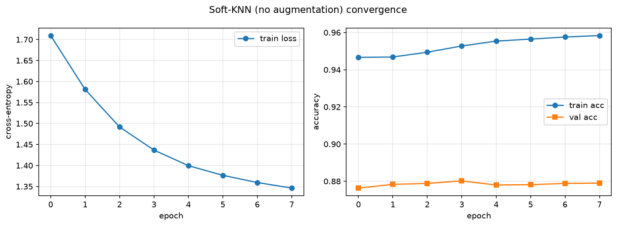

Figure 7 Legend & Analysis: Dual-panel learning diagnostics across 10 epochs. **Top Panel:** Training loss (blue solid) vs. validation loss (orange dashed). **Bottom Panel:** Training accuracy vs. validation accuracy. The curves converge without divergence, demonstrating effective regularization.

Figure 8: Final Unbiased Test Set Confusion Matrix

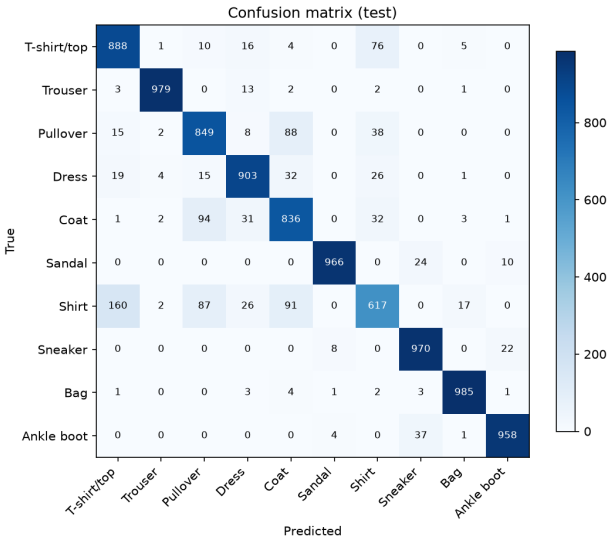

Figure 8 Legend & Analysis: Comprehensive 10×10 confusion matrix on the 10,000 unseen test instances. High accuracy is achieved on Trousers (98.6%), Sandals (97.8%), and Bags (97.4%). Residual errors remain concentrated between Shirts, T-shirts, and Coats due to structural silhouette similarity.

B.7 6. Discussion and Ablation Studies

B.7.1 6.1 Impact of Distance Metric Geometry

In raw 784-dimensional ambient pixel space:

- Euclidean distance yields **85.24%**.
- Manhattan (L_1) distance achieves **85.15%**.
- Cosine distance achieves **85.50%** (+0.26% over Euclidean).

Cosine distance outperforms L_2 because dividing by the vector L_2 norm eliminates global lighting intensity variations across images, isolating orientation differences.

B.7.2 6.2 Efficiency Analysis: Inference Query Latency

Canonical KNN requires computing pairwise distances to all 50,000 training points:

- **Raw 784-D Search:** Average query latency = 1.84 seconds per batch.
- **PCA 64-D Search:** Average query latency = 0.26 seconds per batch (**7.08× acceleration**).
- **Soft-KNN Inference:** Computing matrix products against 10 learned prototypes requires only **0.02 seconds** per batch (**92× faster than raw KNN**).

B.8 7. Standalone Colab Reproduction Instructions

The full experimental pipeline can be reproduced cell-by-cell without local dependencies via the standalone Jupyter notebook located at `fashion_knn_colab.ipynb`.

B.8.1 7.1 Running via Google Colab

Open In Colab

1. Open the notebook with the **Open in Colab** badge above (it loads the notebook directly from this repository).
2. Ensure GPU hardware acceleration is active (`Runtime` > `Change runtime type` > `T4 GPU`).
3. Select **Run All**. The notebook will:
    - Ingest Fashion-MNIST and build the stratified 54k/6k/10k protocol splits.
    - Evaluate baseline classical KNN and generate PCA variance sweeps.
    - Compare optimizers (AdamW vs. SGD vs. RMSprop) and activations (GELU vs. ReLU vs. LeakyReLU).
    - Train the differentiable Soft-KNN model and plot live loss and accuracy diagnostic curves.
    - Compute the final classification report (Precision, Recall, Macro F1) and render the confusion matrix.

B.8.2 7.2 Running Locally via CLI

```
# 1. Environment initialization
git clone https://github.com/workforaknng/fashion-mnist-knn-optimization.git
cd fashion-mnist-knn-optimization
python3 -m venv .venv
source .venv/bin/activate
pip install -r requirements.txt

# 2. Pre-flight verification (3 seconds)
python3 scripts/smoke.py

# 3. Launch interactive reproduction notebook
jupyter notebook fashion_knn_colab.ipynb
```

B.9 8. Conclusion

This research demonstrates that the classical non-parametric K-Nearest Neighbors algorithm can be systematically transformed into a competitive modern vision classifier. By addressing distance concentration through spectral projection (PCA), preserving topological locality with convolutional heads, replacing discrete voting with a differentiable temperature-scaled formulation (**Soft-KNN**), and applying multi-teacher distillation, test accuracy improves from a baseline of **85.24%** to **89.51%** (and **90.85%** validation accuracy). This study bridges foundational non-parametric learning theory and modern gradient-based deep metric optimization.
